## Fundamentals of Robotics, Lecture 8

by Sergei Savin

Fall 2022

Remember Lagrange equations:

$$\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{\mathbf{q}}} \right) - \frac{\partial T}{\partial \mathbf{q}} = \tau \quad (1)$$

Let us remember that in the general case of point masses, kinetic energy is:

$$T = \sum 0.5 m_i \dot{\mathbf{r}}_i^\top \dot{\mathbf{r}}_i, \quad (2)$$

and in the general case of rigid bodies, it is:

$$T = \sum 0.5 m_i \dot{\mathbf{r}}_i^\top \dot{\mathbf{r}}_i + \sum 0.5 \mathbf{w}_i^\top \mathbf{I}_i \mathbf{w}_i, \quad (3)$$

Where  $\dot{\mathbf{r}}_i$  is the velocity of the center of mass of the  $i$ -th body, and  $\mathbf{w}$  is the angular velocity of that body.

# KINETIC ENERGY ENCODING

## Part 1

Using chain rule we can describe the velocity of the center of mass:

$$\dot{\mathbf{r}}_i = \frac{\partial \mathbf{r}_i}{\partial \mathbf{q}} \dot{\mathbf{q}} = \mathbf{J}_i^v \dot{\mathbf{q}} \quad (4)$$

This establishes the connection between  $\dot{\mathbf{r}}_i$  and generalized velocities.

For the rotations, it is not as simple. We start by using a Poisson formula to connect rotation matrix  $\mathbf{T}(\mathbf{q})$  of a body to angular velocity of a body:

$$\mathbf{W}(\mathbf{q}, \dot{\mathbf{q}}) = \mathbf{T}\dot{\mathbf{T}}, \quad \dot{\mathbf{T}}(\mathbf{q}, \dot{\mathbf{q}}) = \frac{\partial \mathbf{T}}{\partial \mathbf{q}} \dot{\mathbf{q}} \quad (5)$$

where  $\mathbf{W}(\mathbf{q}, \dot{\mathbf{q}}) = \begin{bmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{bmatrix}.$

We can create notation:

$$\mathbf{w}(\mathbf{q}, \dot{\mathbf{q}}) = \begin{bmatrix} -\mathbf{W}_{2,3} \\ \mathbf{W}_{1,3} \\ -\mathbf{W}_{1,2} \end{bmatrix} \quad (6)$$

### Homework 1

Prove that  $\mathbf{w}(\mathbf{q}, \dot{\mathbf{q}})$  is linear with respect to  $\dot{\mathbf{q}}$ .

Now we can *find angular velocity Jacobian* of (6) w.r.t.  $\dot{\mathbf{q}}$ :

$$\mathbf{J}_i^w = \frac{\partial \mathbf{w}_i}{\partial \dot{\mathbf{q}}} \quad (7)$$

Since  $\mathbf{w}_i$  is linear w.r.t.  $\dot{\mathbf{q}}$ , we can represent it as:

$$\mathbf{w}_i = \mathbf{J}_i^w \dot{\mathbf{q}} \quad (8)$$

Therefor me can rewrite the kinetic energy in terms of generalized velocity:

$$T = \sum 0.5 \dot{\mathbf{q}}^\top (\mathbf{J}_i^v)^\top m_i \mathbf{J}_i^v \dot{\mathbf{q}} + \sum 0.5 \dot{\mathbf{q}}^\top (\mathbf{J}_i^w)^\top \mathbf{I}_i \mathbf{J}_i^w \dot{\mathbf{q}} \quad (9)$$

Kinetic energy is a *quadratic form* of the generalized velocities. We can define the matrix of the quadratic form:

$$\mathbf{H} = \sum (\mathbf{J}_i^v)^\top m_i \mathbf{J}_i^v + \sum (\mathbf{J}_i^w)^\top \mathbf{I}_i \mathbf{J}_i^w \quad (10)$$

And therefor:  $T = 0.5 \dot{\mathbf{q}}^\top \mathbf{H} \dot{\mathbf{q}}$

We can find derivatives of the kinetic energy (remembering that  $T = T^\top$ , and therefore  $\mathbf{H} = \mathbf{H}^\top$ ):

$$\frac{\partial T}{\partial \dot{\mathbf{q}}} = \mathbf{H} \dot{\mathbf{q}} \quad (11)$$

$$\frac{\partial T}{\partial \mathbf{q}} = 0.5 \dot{\mathbf{q}}^\top \frac{\partial \mathbf{H}}{\partial \mathbf{q}} \dot{\mathbf{q}} \quad (12)$$

Notice that it is very tempting to say that  $0.5 \dot{\mathbf{q}}^\top \frac{\partial \mathbf{H}}{\partial \mathbf{q}} \dot{\mathbf{q}} = 0.5 \dot{\mathbf{q}}^\top \dot{\mathbf{H}}$  but it is *not* the case.  $\frac{\partial \mathbf{H}}{\partial \mathbf{q}}$  is a three dimensional tensor, symmetric along the first and second dimension (so, transposing along these two dimensions doesn't change the products of the tensor with matrices or vectors). Multiplication by  $\dot{\mathbf{q}}$  happens along the first and second dimensions, while the partial differentiation happens along the third dimension, therefore the result is not necessarily equals to  $0.5 \dot{\mathbf{q}}^\top \dot{\mathbf{H}}$ .

Left-hand side of the Lagrange equations can be re-written as:

$$\frac{d}{dt} \left( \mathbf{H} \dot{\mathbf{q}} \right) - 0.5 \dot{\mathbf{q}}^\top \frac{\partial \mathbf{H}}{\partial \mathbf{q}} \dot{\mathbf{q}} = \tau \quad (13)$$

We can expand the derivative of a product:

$$\mathbf{H} \ddot{\mathbf{q}} + \dot{\mathbf{H}} \dot{\mathbf{q}} - 0.5 \dot{\mathbf{q}}^\top \frac{\partial \mathbf{H}}{\partial \mathbf{q}} \dot{\mathbf{q}} = \tau \quad (14)$$

Expression  $\dot{\mathbf{H}} \dot{\mathbf{q}} - 0.5 \dot{\mathbf{q}}^\top \frac{\partial \mathbf{H}}{\partial \mathbf{q}} \dot{\mathbf{q}}$  is often cast as a linear form.  $\mathbf{C} \dot{\mathbf{q}}$   
The classic formula for calculating  $\mathbf{C} \dot{\mathbf{q}}$  uses Christoffel symbols.

Christoffel symbols-based formula for the  $\mathbf{C}\dot{\mathbf{q}}$  is:

$$\mathbf{C}\dot{\mathbf{q}} = \begin{bmatrix} \sum_{j,k}^n \Gamma_{1,j,k} \dot{q}_j \dot{q}_k \\ \dots \\ \sum_{j,k}^n \Gamma_{n,j,k} \dot{q}_j \dot{q}_k \end{bmatrix} \quad (15)$$

where Christoffel symbols  $\Gamma_{i,j,k}$  are given as:

$$\Gamma_{i,j,k} = \frac{1}{2} \left( \frac{\partial H_{i,j}}{\partial q_k} + \frac{\partial H_{i,k}}{\partial q_j} - \frac{\partial H_{k,j}}{\partial q_i} \right) \quad (16)$$

My apologies for not providing a derivation

Sometimes we need to find matrix  $\mathbf{C}$  specifically, rather than linear form  $\mathbf{C}\dot{\mathbf{q}}$ . This can be achieved using Christoffel symbols as well.

$$C_{i,j} = \sum_k^n \Gamma_{i,j,k} \dot{q}_k \quad (17)$$

If you use auto-differentiation, you can consider directly using expression (14) to find  $\mathbf{C}\dot{\mathbf{q}}$ :

$$\mathbf{C}\dot{\mathbf{q}} = \dot{\mathbf{H}}\dot{\mathbf{q}} - 0.5 \frac{\partial \dot{\mathbf{q}}^\top \mathbf{H} \dot{\mathbf{q}}}{\partial \mathbf{q}} \quad (18)$$

In Matlab code it looks like:

```
0 C_times_v = reshape(dHdt*v, length(v), 1) - reshape  
jacobian((0.5*v' * H * v), q), length(v), 1);
```

Alternatively, you can use the following formula:

$$\mathbf{C}\dot{\mathbf{q}} = \dot{\mathbf{H}}\dot{\mathbf{q}} - 0.5 \frac{\partial \text{vec}(\mathbf{H})}{\partial \mathbf{q}} (\dot{\mathbf{q}} \otimes \dot{\mathbf{q}}) \quad (19)$$

where  $\otimes$  is a Kronecker product, and  $\text{vec}()$  is vectorization of matrix (representing all its elements as a vector).

In Matlab code it looks like:

```
0 C_times_v = reshape(dHdt*v, [], 1) - 0.5*( jacobian(  
    reshape(H, [], 1), q)'*kron(v, v) );
```

# GENERALIZED FORCES

## Part 1, General case

You can express generalized forces of all kinds using discussed previously multiplication by the Jacobian:

$$\tau = \left( \frac{\partial \mathbf{r}}{\partial \mathbf{q}} \right)^\top \mathbf{f} \quad (20)$$

where  $\mathbf{f}$  is an external force, and  $\mathbf{r}$  is the radius-vector giving position of that force.

For a torque  $\xi$  applied to a rigid body, the corresponding generalized force is:

$$\tau = \mathbf{J}_w^\top \xi \quad (21)$$

where  $\mathbf{J}_w$  is the angular velocity Jacobian of that body. Note that both  $\mathbf{J}_w$  and  $\xi$  need to be expressed in the same basis.

# GENERALIZED FORCES

## Part 2, Conservative forces

If the force is conservative, it is often easy to describe potential energy  $U$  associated with it. Then you can find the relevant generalized forces as:

$$\mathbf{g} = -\frac{\partial U}{\partial \mathbf{q}} \quad (22)$$

Typically this is useful for gravitational forces and elastic forces.

Finally we can write the form of manipulator equations:

$$\mathbf{H}\ddot{\mathbf{q}} + \mathbf{C}\dot{\mathbf{q}} = \boldsymbol{\tau} \quad (23)$$

Another popular form specifically points out conservative forces  $\mathbf{g}$ :

$$\mathbf{H}\ddot{\mathbf{q}} + \mathbf{C}\dot{\mathbf{q}} + \mathbf{g} = \boldsymbol{\tau} \quad (24)$$

The most concise and useful for this class form is:

$$\mathbf{H}\ddot{\mathbf{q}} + \mathbf{c} = \boldsymbol{\tau} \quad (25)$$

where  $\mathbf{c} = \mathbf{C}\dot{\mathbf{q}} + \mathbf{g}$ .

Importantly, manipulator equations can always be re-written in an explicit form (where the highest-order derivative is isolated on the left-hand-side):

$$\ddot{\mathbf{q}} = \mathbf{H}^{-1}(\boldsymbol{\tau} - \mathbf{C}\dot{\mathbf{q}} - \mathbf{g}) \quad (26)$$

This is possible because  $\mathbf{H}$  is full-rank. This in turn is possible, because generalized coordinates are independent.
